## INTRODUCTION

TENPIN is an electronic game that makes extensive use of digital integrated circuits. This manual assumes that the maintenance technician possesses a general knowledge of solid-state circuitry and TTL digital integrated circuits. Any individual not knowledgeable in this area should not attempt to repair the electronic portions of the game. IT SHOULD BE NOTED THAT ANY ATTEMPT TO REPAIR THE GAME IN THE FIELD WITHOUT THE EXPRESS CONSENT OF THE FACTORY WILL IMMEDIATELY VOID THE WARRANTY!

### IMPORTANT NOTES:

NEVER replace any component with anything other than an EXACT replacement part. This includes LAMPS, TRANSISTORS, INTEGRATED CIRCUITS, and the like.

LAMPS used in this game are #1813, which operate at 14.4 volts, 100 ma. and #756 lamps which operate at 14.4 volts, 80 ma. NEVER use a lamp that operates at a lower voltage or higher current. To do so will very likely damage the circuitry in the game.

DO NOT use metal objects (screwdrivers, pliers, etc.) around the lamp sockets with the game turned "ON". The outer shell of the sockets have voltage on them, and shorting them to each other or to other points on the game will damage the circuitry.

DO NOT replace the fuse with anything other than the proper value. A blown fuse indicates an overload condition within the game. Replacing the fuse with a larger value can cause severe damage to internal components if an overload occurs.

ALWAYS consult the manual before attempting any repairs.

CORRESPONDENCE regarding this game should be addressed to:

GREMLIN INDUSTRIES, INCORPORATED  
8401 Aero Drive  
San Diego, California 92123

Phone: 714-277-8700

UNPACKING AND INSPECTION:

The TENPIN Game is normally shipped in a single package containing the game main frame and the accessory kit, which consists of the coin box, transmitter and associated parts.

The box must be opened immediately upon arrival and inspected for freight damage. It is advisable to connect the game for operation and determine that it is operating properly, as some freight damage can occur within the main frame and not be immediately evident during a cursory visual inspection.

If damage has occurred during shipment, the recipient should immediately file a damage claim with the carrier. Filing a claim will protect the recipient from bearing the full cost of any repairs that may arise from the damage.

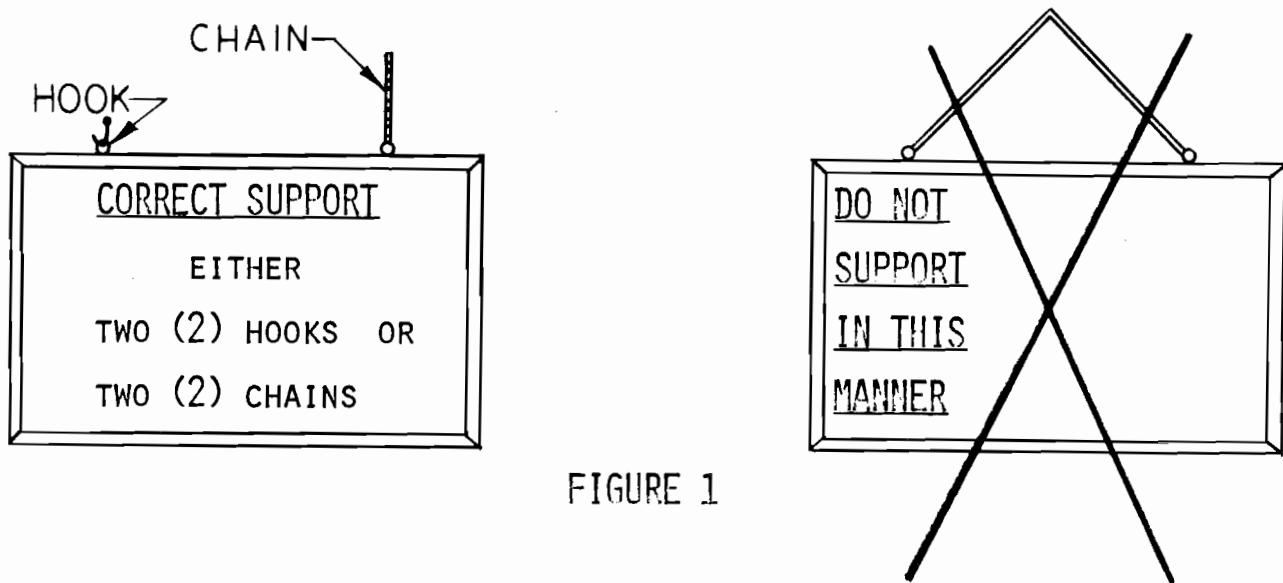

Any game or accessory claimed to be defective must be returned to GREMLIN INDUSTRIES, INC., 8401 Aero Drive, San Diego, California 92123, transportation charges prepaid. The game will be repaired and returned to the customer, transportation charges prepaid, if still within the warranty period. If the game is found to be damaged by misuse, improper attempts at repair, or abuse, it will be returned to the customer with transportation and repair charges billed.

In the instance of a defect of sub-assemblies or assemblies manufactured by other than GREMLIN INDUSTRIES, every effort will be made to assist the customer in obtaining satisfaction from the original manufacturer.

## INSTALLATION PROCEDURE

- 1.) The game is designed to be supported from two points by either hooks or chains (Refer to FIGURE 1. ).

IMPORTANT: The game should not be supported by a single hanger.

- 2.) The coinbox can be mounted in any convenient location and is connected to the game by means of the 10-pin molex connector provided.

After mounting the coinbox (insuring the cable will reach the game), connect the coinbox as follows:

- Open front screen of game.
- Connect game as illustrated in FIGURE 2.

IMPORTANT: Insure that the coinbox cable is placed in the feed-through hole provided before attempting to secure the front display screen.

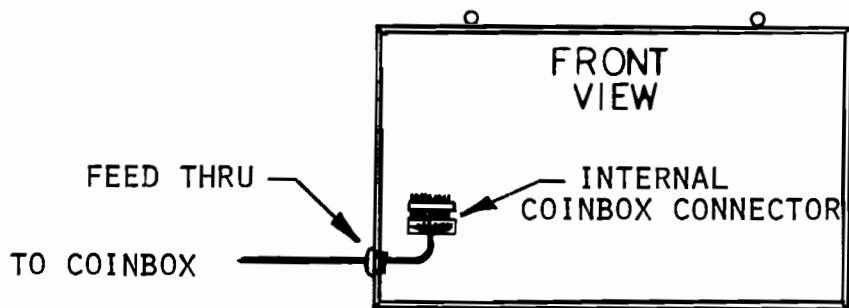

FIGURE 2

## MAINTENANCE

The following are recommendations for the care of your GREMLIN wall game. These recommendations are of a non-technical nature. For technical information refer to other sections of this manual.

### 1.) CLEANING

GREMLIN recommends using an all purpose commerical cleaner such as 409 (or equivalent) for all exterior surfaces.

### 2.) LAMP REPLACEMENT

Lamps should only be replaced with exact replacements. TENPIN uses #756 and #1813 lamps (12-14 volts, 100 ma), any attempt to use lamps other than ones specified could cause electrical damage and void the game warranty.

IMPORTANT: Always remove power from the game before replacing lamps. The outer shell of the socket has voltage applied and shorting these points to ground can cause damage to the circuitry.

### 3.) LOGIC BOARD REPLACEMENT

If, for any reason, the logic or sound board in your game needs to be replaced the same rule applies as for lamp replacement: ALWAYS REMOVE POWER from the game!

### TENPIN GAME DESCRIPTION

The TENPIN game is a single, wall-mounted unit that needs only an external coinbox and transmitter (control box) to operate. Both of the latter units are supplied with the game.

Within the main frame of the game assembly is a large (2.5 feet by 5.0 feet) printed circuit lamp board, which contains plug-in provisions for the power/sound board and the logic board. Additionally, a receiver module is incorporated on the front of the lamp board to receive and process the signals transmitted from the hand-held transmitter control.

The transmitter/controller is a standard, tone-modulated 49 MHZ transmitter. The only control necessary for its operation is the top-mounted push button that is actuated to play the game.

The coinbox provided with the game is a quarter acceptor type that causes a switch contact closure with each coin inserted. Each coin activates the circuitry in the main frame and allows a game to be played.

The game is played in the following manner:

- 1.) Two players normally compete in TENPIN, each taking turns at the control box that enables them to play from any place in the room. An option is incorporated to allow single player games.
- 2.) A coin is deposited and the game activates, allowing the transmitter control box to initiate action.
- 3.) A triangle indicator moving back and forth across the alley represents 15 possible ball paths which determine the number of pins knocked down on each ball roll. The first player depresses the control button, which stops the movement of the triangle and initiates the ball roll. Depending on how skillfully the player selects the ball path on the first ball, the player may be awarded a strike (20 points; one point per pin plus a 10 point bonus) or a gutter ball (zero points) or anywhere from one to nine points (one point per pin). If the player does not get a strike on the first ball, a second ball is awarded and "Roll Again" will light up. The player can then try to knock down the remaining pins. If the player is successful, he will be awarded a spare (15 points; one point per pin plus a 5 point bonus). Points are awarded for pins knocked down and any pins left standing after the second ball will not score points.

- 4.) When the ball is rolled a realistic sound of the ball rolling down the alley and hitting the pins is generated. If the ball fails to knock down any pins, a frog croak is generated. When a strike is rolled there is a sharp clap of thunder, Rip awakens, and the bowler is saluted by the merrymakers.
- 5.) A free game is awarded when a preselected score is attained or exceeded by either player during the period of a game. This score is selected by a switch on the front of the lamp board.
- 6.) TENPIN is internally programmable to allow control over the speed of the triangle sequencing and the ball roll.
- 7.) The length of the game is controlled by the number of frames to be played and is selected by a rotary switch on the front of the lamp board. The switch is accessed by opening the front display panel.

## TENPIN GAME PROGRAMMING AND ADJUSTMENTS

### LOGIC BOARD

There are two program adjustments and two speed adjustments on the TENPIN Logic Board, P/N 812-0001. They are:

#### 1. THE NUMBER OF COINS NECESSARY FOR A GAME CREDIT.

For single coin credits a jumper wire must connect Pins E1 and E3 (this is the factory setting). If two coins for a game credit is desired then the jumper should connect Pins E1 and E2. Only one jumper should be in place at a time.

#### 2. THE NUMBER OF PLAYERS PER CREDIT.

For single player per credit a jumper wire must connect Pins E4 and E5 (in this configuration one credit gives a single player game and two credits give a two player game).

For two players per credit a jumper wire must connect Pins E4 and E6 (this is the factory setting and in this configuration no single player game is possible). Only one jumper should be in place at a time.

#### 3. TRIANGLE SPEED ADJUSTMENT.

The triangle speed adjustment is potentiometer R6 and it controls the speed at which the triangle ball path indicators oscillate back and forth across the alley. Speeding up the triangles makes it more difficult to pick the optimum path and therefore makes the game more difficult to play. Slowing down the triangles makes the game easier.

## TENPIN GAME PROGRAMMING AND ADJUSTMENTS (Continued)

### LOGIC BOARD (Cont'd.)

#### 4. MASTER CLOCK ADJUSTMENT.

The master clock adjustment controls most of the timing/counting functions of the game, such as the ball roll speed, but does not change the length or difficulty of the game. This potentiometer R1 is factory set and does not require adjustment under normal circumstances.

### LAMP BOARD

There are two game program adjustments that are accessible from the front of the lamp board and they are:

#### 1. "END OF GAME FRAME" SWITCH.

This four position switch selects the last frame for the end of the game. It selects either 10, 9, 8, or 7 frames per game.

#### 2. THE "FREE GAME FOR" SWITCH.

This eight position switch selects the minimum number of points at least one player must have to be awarded a free game. It selects scores of 130 points thru 190 points.

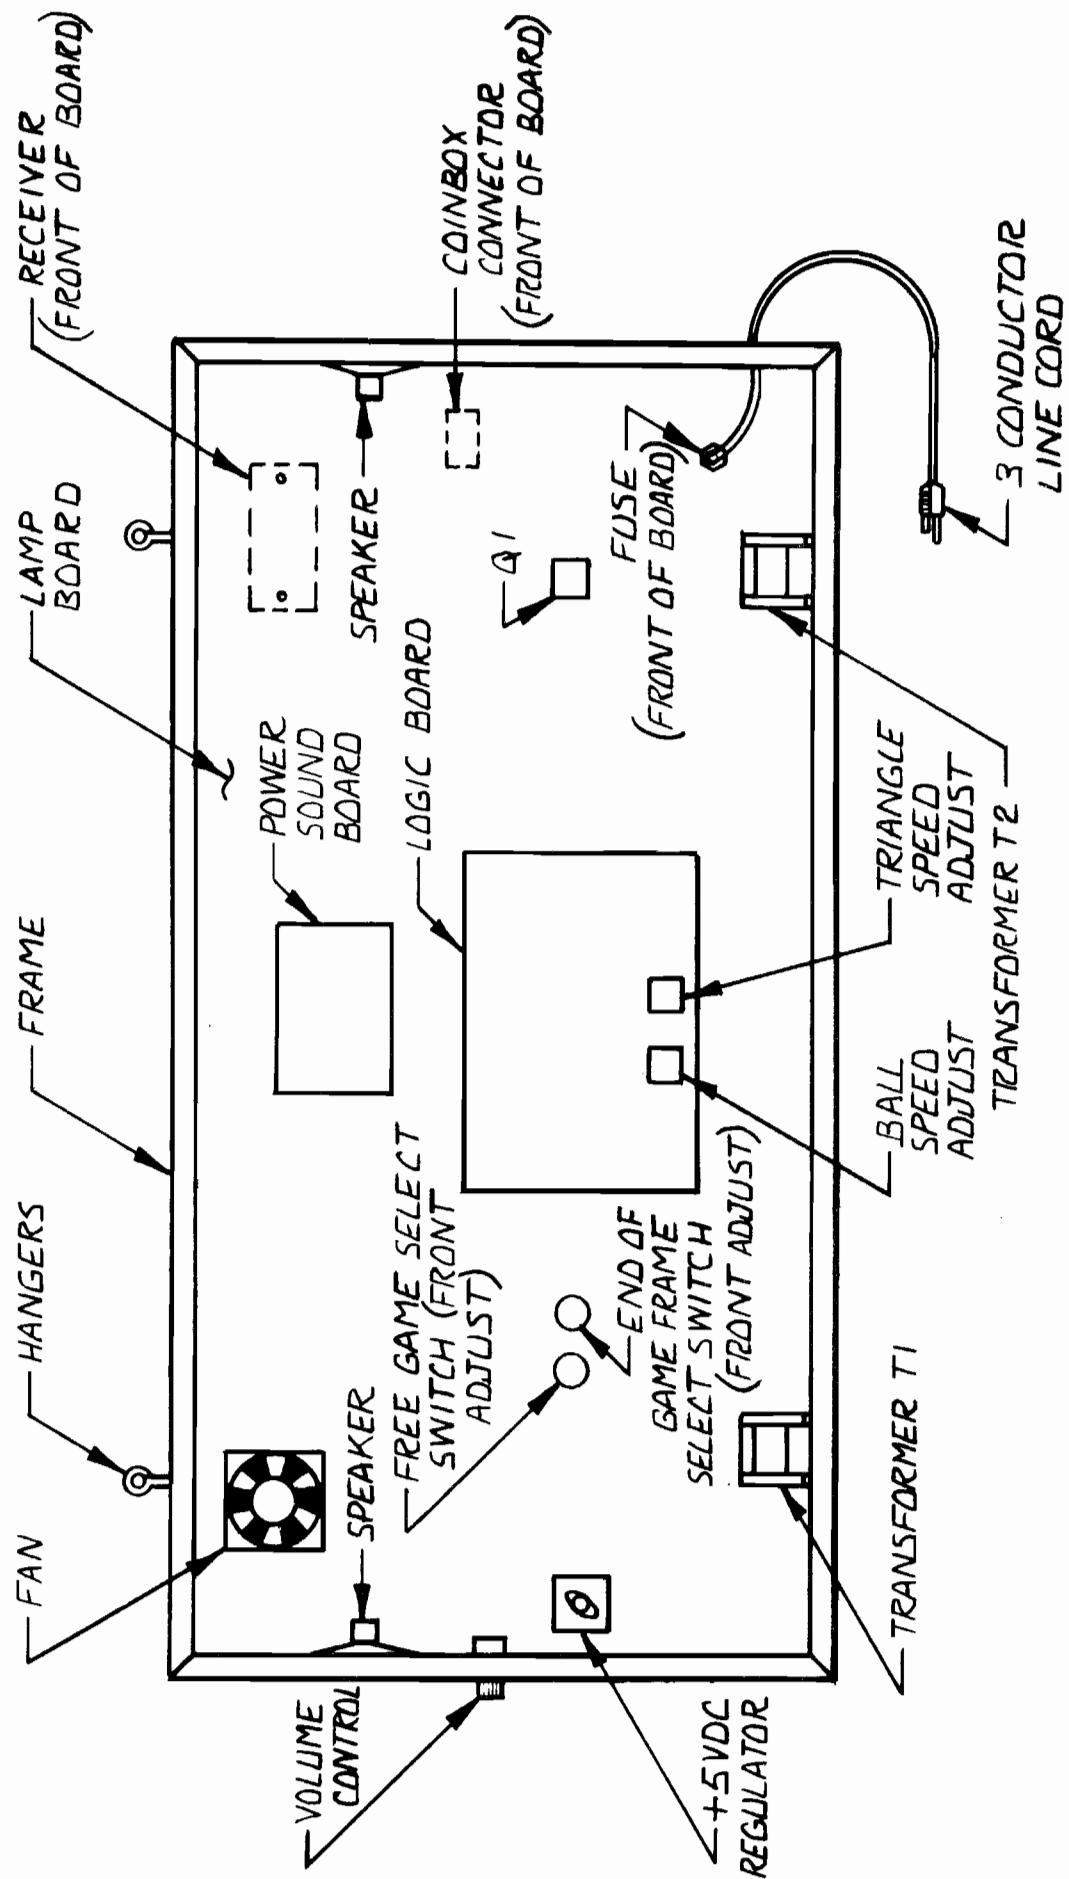

FIGURE 3  
LAYOUT DIAGRAM  
(REAR VIEW OF GAME)

## SYSTEM DESCRIPTION

TENPIN is a digitally controlled, sequentially animated game. Digital integrated circuits control the rate, interval, and sequence of events.

Figure 4 is a simplified block diagram of the game. The Credit is applied to the End of Game circuit when a valid coin drop is received by the Coin Discriminator which activates the Triangle Motion/Selector and allows it to begin cycling.

The Receiver output will now stop the cycling of the Triangle Motion/Selector circuit and select a ball path dependent upon the triangle(s) which were lit when the transmitter pushbutton was depressed.

The Triangle Motion/Selector starts the Ball Motion circuit, which rolls the ball down the alley, and inputs to the Pin Proms, which select pins knocked down, and the Score Proms, which add up proper scoring and display it. The Score Proms output to the proper player (1st Up or 2nd Up). The End of Game circuit keeps track of the number of ball rolls.

The 1st Up Score and 2nd Up Score are applied to the Free Game Selector and if either score is high enough to equal or exceed the score selected by the "FREE GAME FOR" switch, a Free Game is awarded and inhibits the End of Game circuit from inactivating the Triangle Motion/Selector, but does reset Frame Counter, 1st Up Score and 2nd Up Score to zero.

The End of Game Selector is activated when the Frame Counter reaches the number selected by the "END OF GAME" switch. The End of Game circuit receives this signal and resets the entire game to zero and awaits another coin drop.

The Power on Delay circuit resets the End of Game logic on initial plug in of the game power cord. This is necessary to clear all of the logic to its zero state.

TENPIN SIMPLIFIED BLOCK DIAGRAM

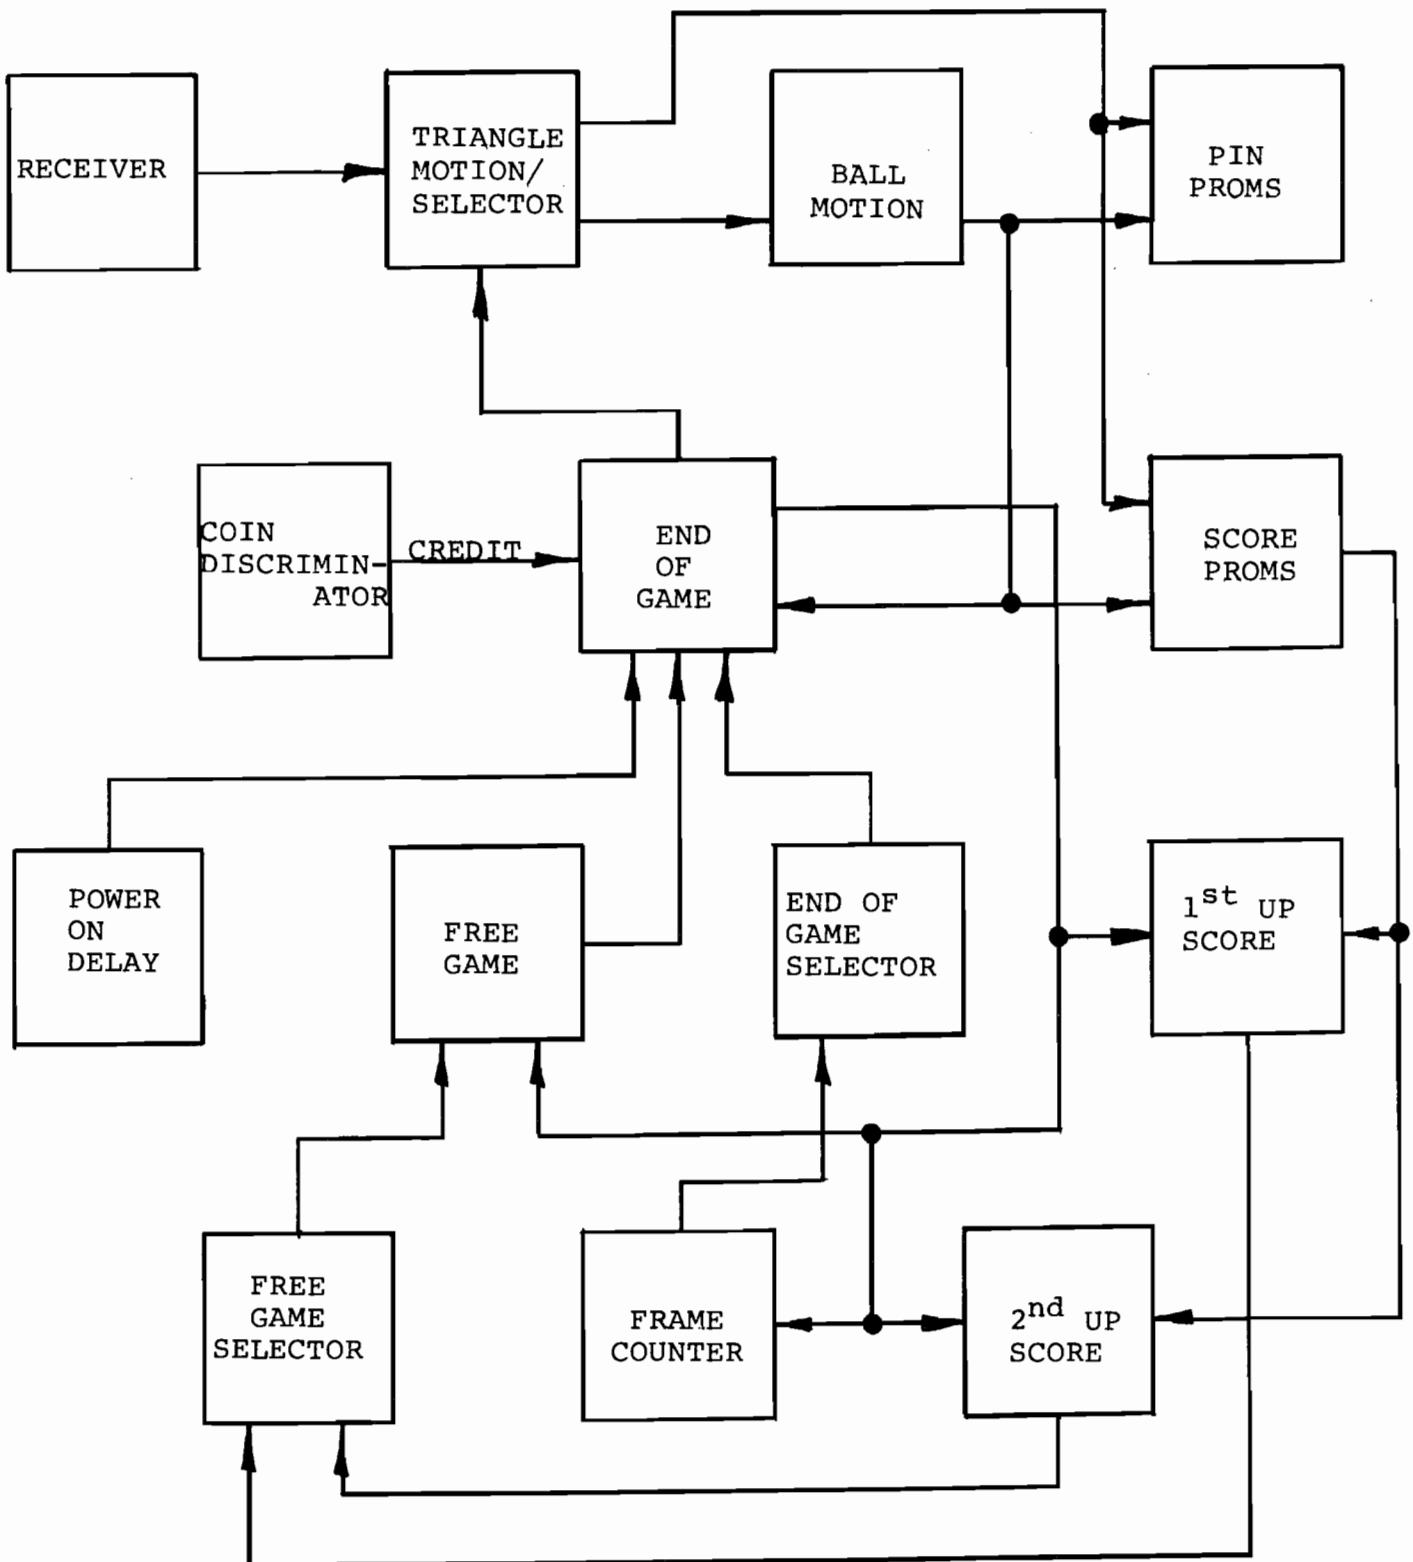

FIGURE 4

## TENPIN SOUND EFFECTS AND POWER CONTROL

The sound effects developed for TENPIN are unique and contribute to the life-like action of the game. The four basic sounds and power buss control are described below.

For the following discussion refer to the Power/Sound Board Schematic.

### PIN & PIN BACKGROUND SOUNDS

The Strike and Hit sounds are very similar; the basic difference being that the Strike sound is 800 ms long and the Hit sound is 500 ms long.

When a Strike occurs a High is applied to pins 22 and 25 of the Power/Sound Board. When a Hit occurs a High is applied to pin 22 only. As a result, a High of appropriate length appears at pin 3 of U2.

This one-shot action causes the following: First, the leading edge at pin 3 is coupled to Q4 and C6 thus quickly charging C7. The voltage on C7 decays slowly and amplitude modulates the 200Hz noise at the base of Q16. An amplified version then appears at pin 8 of U7 and is summed into the audio output by R138, supplying background noise for the pins falling. Next, the logic High from U2 enables the oscillator of U10. When the oscillator output is High, Q34 and Q31 are turned on and C46 begins to charge. When the

output goes Low, Q32 is turned on and C46 begins to discharge. The resulting waveform is buffered by Q33 and applied to the frequency modulation pins of oscillators U12, U13, and U14.

The frequency of each oscillator is vastly different. This fact coupled with the frequency modulation applied to the oscillators serves to create a psuedo-random event generator that has the cadence of bowling pins falling.

Both the leading and trailing edges of the oscillator outputs are capacitively coupled and appear at R150 and R158. R150 is the input to a three stage resonant filter that has a Q of 100 and a resonant frequency of 1200 Hz. R158 is the input to a single stage resonant filter with a Q of 10 and a resonant frequency of 200 Hz.

Noise with a cut-off frequency of 1200 Hz is applied to the base of Q25 and modulated by the sawtooth appearing at the base of Q24. The resulting modulated noise is injected into the 200 Hz resonant filter at R157.

When a resonant filter receives an impulse, it tends to oscillate at its resonant frequency. The sharp rise and decay of those oscillations, plus the noise applied to the 200 Hz filter, reproduce the familiar wood sound of bowling pins falling. The oscillations from the two filters are summed through R162 and R164 at the summing amplifier of U6 and summed into the final audio at R142.

### BALL ROLL

The Ball Roll is reproduced by applying 200 Hz noise to the base of the amplifier Q10. Q10 is gated on and off with Q11. A Low from the Logic Board at pin 23 turns Q10 on. A High turns it off. R36 and R37 provide Q10 with the correct d.c. bias. R38 and R39 set the amplifiers gain to unity. The Ball Roll is summed with the rest of the audio through R139.

### FROG CROAK

Whenever a player bowls either a Miss or a Gutter, the Frog croaks the player's misfortune.

A Low at pin 24 of the Sound Board is inverted by Q9 and applied to pin 10 of U4. Pin 9 of U4 produces an oscillation which is High for 50 ms and Low for 200 ms. When pin 9 of U4 is High it enables the oscillator at pin 4 of U4. Thus, pin 5 of U4 oscillates with a frequency of about 20 Hz. R24 couples these oscillations to the resonant filter of U7, R51, R52, C27 and C28.

The FET at pin 13 of U7 shifts the frequency response of the filter. When pin 9 of U4 goes High, C26 is quickly charged and the FET turns on. As the voltage at C26 decays, the FET gradually turns off and lowers the resonant frequency of the resonant filter. The Frog Croak is summed with the rest of the audio through R140.

## THUNDER

The Thunder occurs during a strike and is initiated by a High going pulse at pin 21 of the Sound Board.

The Thunder sound is created by applying very low frequency noise to the base of Q29 and modulating it with a slowly decaying exponential voltage applied to the base of Q30. An amplified version of the signal appears at pin 1 of U5 and is summed with the rest of the audio through R141.

## POWER BUSSES

In order to cut the parts count and make the game more reliable, a buss switching system is used in TENPIN. When a game is initiated a logic High is applied to pin 40 of the Sound Board. This applies power to one side of the Pins UP lamps. The individual lamps are lighted by grounding the other side of the lamps through a transistor.

The three Ball Path busses have power applied to them by the Triangle sequence. When the Triangle sequence is at the top, Ball Path Buss A is enabled (a High is applied to Pin 38 of the Sound Board), when it is near the middle, Buss B is enabled, etc.

As the Ball Path is sequenced, triplets of lamps are grounded through a single transistor but only one lamp is lighted because only one Ball Path power buss is enabled at any given time.

### GENERAL ILLUMINATION DIMMING

When a game is not in progress the Logic Board sends a logic High to pin 1 of the Sound Board. This grounds the anode of D1 through Q7. Q1 on the Lamp Board is robbed of its gate bias and turns off.

As the rectified a.c. at pins 5 and 6 begins to rise, C1 charges through R4. When the voltage on C1 exceeds 5V Q2 and Q3 conduct and supply gate current to Q1. Q1 then conducts until the voltage at C1 drops below 5V. The effect is to drop the rectified a.c. lamp voltage and dim the General Illumination lamps thus saving power and extending lamp life.

### AUDIO AMP

The Audio Amplifier used in TENPIN is of the quasi-complimentary type. R88, D8 and R92, D9 provide voltage biasing in order to prevent cross over distortion. Q19 and Q20 drive the two TIP 29s which are capable of delivering 10 watts to a 16 ohm load. R86 and R84 set the mid-frequency gain to 11 while C51 gradually rolls the gain off at high frequencies. C55 rolls off the low frequency gain and R87 insures that the amplifier output is always zero when no signal is applied to the input. The summing amplifier of U6 sums all of the audio inputs while C69 blocks and d.c. component of the summed signal.

The volume control (Lamp Board R3) is externally located in order to accommodate any ambient noise level. The summed audio output appears at pin 11 of the Sound Board and is electrically connected to the volume control through the lamp board. The attenuated audio returns to pin 12 of the Sound Board (again via the Lamp Board) and is amplified for output to the two series connected loudspeakers.
